

Papilio: Papilio One Hardware

Hardware | Papilio One - Papilio Pro - MegaWings - Wings

Papilio One

The Papilio is an Open Source FPGA development board based on the Xilinx Spartan 3E FPGA (datasheet). It has 48 I/O lines, dual channel USB, integrated JTAG programmer, 4 power supplies, and a power connector. It provides everything needed to start learning Digital Electronics.

Features

Power

- Four independent power rails at 5V, 3.3V, 2.5V, and 1.2V.
- Power supplied by a power connector or USB.
- DC Input Jack.
 - Input Voltage (recommended): 6.5-10V

USB

- Two channel USB connection for JTAG and serial communications implemented with FT2232D.
- EEPROM memory to store configuration settings for FT2232 USB chip.

Spartan 3E FPGA

- 32MHz oscillator that can be used by Xilinx's DCM to generate any required clock speed.
- VTQFP-100 footprint that supports Xilinx XC3S100E, XC3S250E, and XC3S500E parts.
- I/O can be set to support 1.2V, 2.5V, or 3.3V.

SPI Flash

- 4M SPI Flash

Wings

- 48 bidirectional I/O lines which can be split up as:
 - 1x 32 Bit Wing or
 - 3x 16 Bit Wings or
 - 6x 8 Bit Wings
- .1" spacing for compatibility with bread boards.

Dimensions

- 2.7"x2.7"

Xilinx Spartan 3E

The Spartan 3E FPGA used in the Papilio One offers some exciting features:

Multi-Voltage

With the VCCO Select header built into the Papilio voltages of 1.2V, 2.5V, and 3.3V can be used.

Digital Clock Manager (DCM)

Easily generate any clock from 5Mhz to 300Mhz using the DCM clock wizard. 4 DCM's allow you to generate many clocks from the external 32Mhz Oscillator included on the Papilio One board.

Multiple Signal Standards

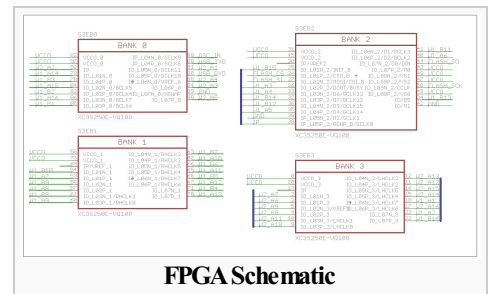

LVC MOS, LVTTTL, HSTL, differential pairs for LVDS, mini-LVDS

Boot from SPI Flash

The Spartan 3E boots from an industry standard SPI Flash device included on the Papilio One board.

BRAM Memory Blocks

The Spartan 3E includes fast, dual-port, internal SRAM called Block RAM.

FPGA Schematic

Papilio Board	18Kbit BRAM Blocks	Max SRAM	Usable SRAM
Papilio Pro	32	576Kbit (72KByte)	512Kbit (64KByte)
Papilio One 500K	20	360Kbit (45KByte)	320Kbit (40KByte)
Papilio One 250K	12	216Kbit (27KByte)	192Kbit (24KByte)

BRAM's are 18Kbit in size including two parity bits. In most cases the two parity bits are not used so the BRAM's usable size becomes 16Kbit. If your design can use an 18 bit wide bus then it is possible to utilize the parity bits for data and gain access to all 18Kbit memory space.

Power

The Papilio One can be powered from the USB connector, an external power supply, or a battery. The PWRSELECT jumper controls whether the USB connector or the Power Jack/PWRIN connectors are active.

Power Selection

When the USB connector is selected up to 500mA of current is supplied to the 1.2V, 2.5V, and 3.3V LD1117 voltage regulators. The 5V power rail is supplied directly by the USB port and the 5V LD1117 power regulator is inactive.

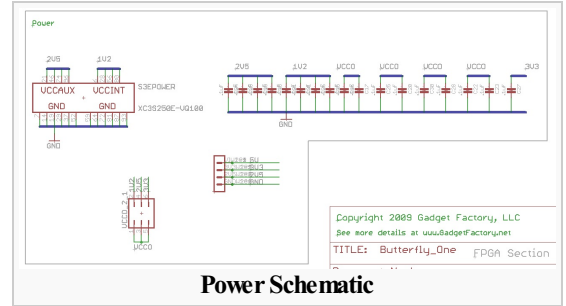

When the power jack or battery is selected the 5V LD1117 voltage regulator supplies up to 800mA of current to the 1.2V, 2.5V, and 3.3V LD1117 voltage regulators. The power jack or battery must provide at least 6V in order to generate the desired 5V output.

Power Jack

- Input: 6-15V DC
- Current: Draws up to 800mA
- Size: 2.1mm
- Polarity: Positive Tip

RPAR

The JTAG programming pins on the Spartan 3E always operate at 2.5V while the connected JTAG pins of the FT2232D always operate at 3.3V. This difference in voltage can cause the Spartan 3E to send reverse current back on the 2.5V power rail. The RPAR resistor provides a shunt for this reverse current to be dissipated. The Xilinx application notes recommend the use of RPAR in the case that a voltage regulator cannot handle reverse current. The LD1117 datasheet does not indicate that it can handle reverse current so RPAR was included. Testing has shown that the LD1117 seems to handle the reverse current just fine but boards will be populated with RPAR as a safety precaution. The RPAR resistor consumes 25mA of current so if a battery is being used it is recommended to remove the RPAR resistor to help extend battery life. Please understand that the possible effects of removing the RPAR resistor are the 2.5V rail going higher than 2.5V and possibly damaging the 2.5V voltage regulator. There is an interesting discussion about the need for RPAR [here](#).

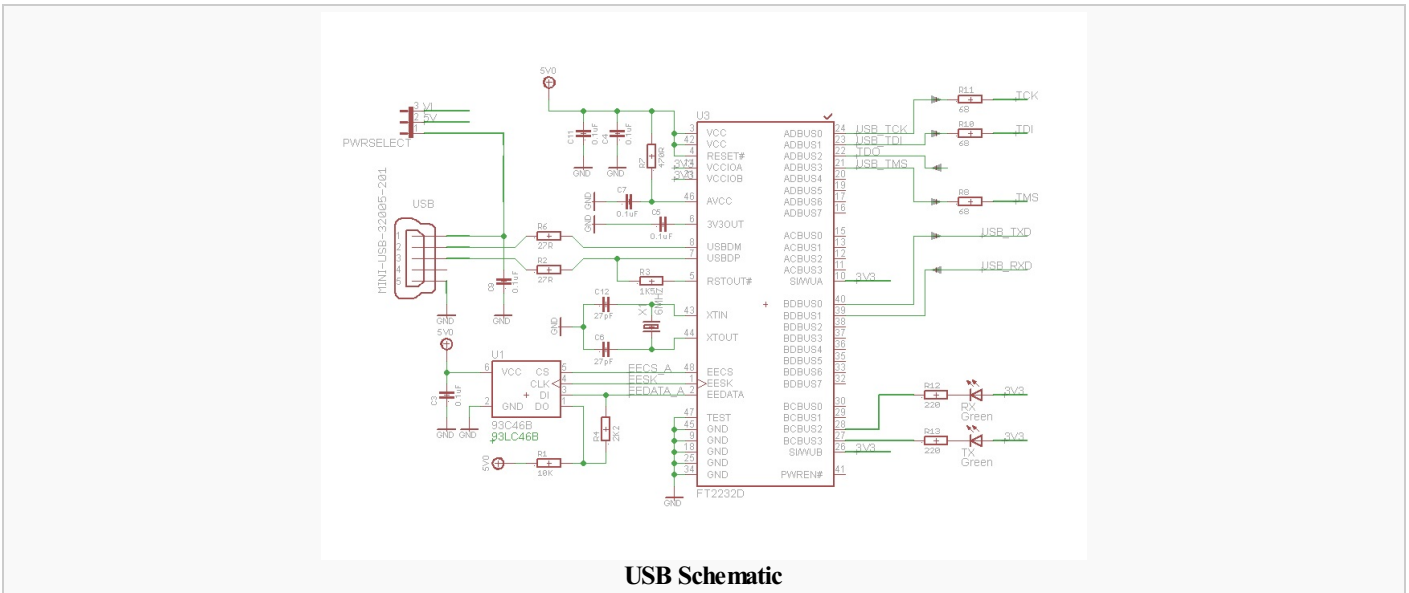

Dual Channel USB

The Papilio One uses the FT2232 dual channel USB chip for JTAG programming and Serial UART communications.

- Channel A is connected to the Papilio One in an Asynchronous serial UART configuration that is capable of speeds up to 2MHz
- Channel B is connected to the JTAG pins of the Papilio One and provides very fast programming of the FPGA (500ms).

Name	Direction (FPGA Perspective)	Function	Arduino Pin	Papilio Wing Pin	Papilio One Pin
RX	Input	FPGA Serial Receive (MISO)	N/A	N/A	P88
TX	Output	FPGA Serial Transmit (MOSI)	N/A	N/A	P90

SPI Flash

The 4Mbit SST SST25VF040B SPI Flash chip provides plenty of space for a boot

bit file and user data. Any bit file written to SPI Flash using the **Papilio Loader** tool will automatically startup when power is applied.

Name	Direction (FPGA Perspective)	Function	Arduino Pin	Papilio Wing Pin	Papilio One Pin
FLASH_CS	Output	SPI Flash Chip Select	N/A	N/A	P24
FLASH_CLK	Output	SPI Flash Clock	N/A	N/A	P50
FLASH_MOSI	Output	SPI Flash Master Out Slave In (MOSI)	N/A	N/A	P27
FLASH_MISO	Input	SPI Flash Master In Slave Out (MISO)	N/A	N/A	P44

I/O

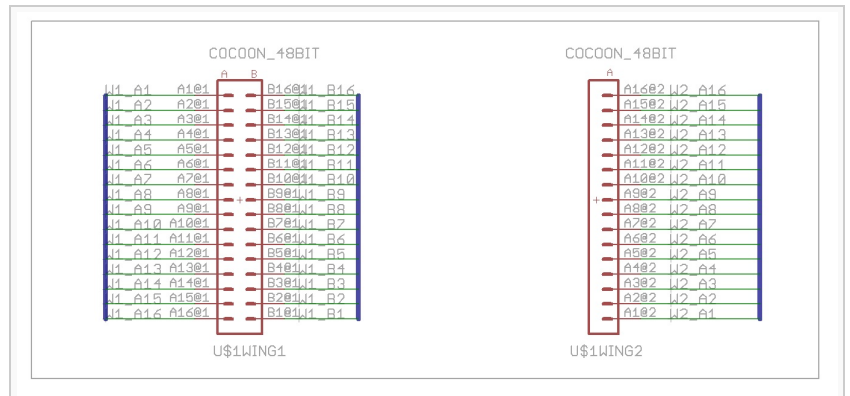

I/O Blocks

The I/O blocks provides programmable interface between pins and the Spartan-3E internal logic.

- Programmable pull-down, pull-up and float resistors (Pull-down by default on unused pins).
- Programmable input delay.
- Optional keeper circuit (keeps last logic level, see spartan-3E datasheet page 18).
- 2 to 16 mA programmable output current drive strength.
- All I/O pins are in high-impedance state during configuration (program loading). Unused pins are pull-down inputs by default with the Xilinx ISE software.

I/O Banks

The VCCO jumper selects the voltage for all of the I/O lines, the options are 1.2V, 2.5V, and 3.3V. The recommended setting is 3.3V since most peripherals operate at 3.3V.

Oscillator

The Papilio One has a 32Mhz oscillator that can be converted to any speed desired inside the FPGA using the Digital Clock Manager (DCM). There are four **Digital Clock Managers (DCM)** available for your designs.

Name	Direction (FPGA Perspective)	Function	Arduino Pin	Papilio Wing Pin	Papilio One Pin
CLK	Input	External 32Mhz Oscillator	N/A	N/A	P89

JTAG

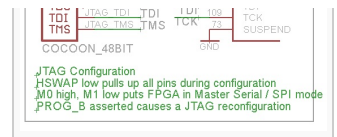

The JTAG header on the Papilio One is provided so external JTAG programmers can be used:

Use a **Xilinx Programming Cable**

If you want to use the Xilinx tools such as EDK, Chipscope, or Impact with the Papilio you need a way to use a Xilinx programming cable. The Papilio has a Xilinx JTAG header but the problem is that in the default mode the FT2232D USB chip is connected to the JTAG pins and interferes with programming. What is needed is to put the FT2232 into a mode where the JTAG pins go into High-Z leaving the Xilinx JTAG pins free for the programming cable. To learn more about using a Xilinx Programming Cable visit the [original forum post](#) or [blog post](#).

Name	Direction (FPGA Perspective)	Function	Arduino Pin	Papilio Wing Pin	Papilio One Pin
JTAG_TMS	Input	JTAG TMS	N/A	N/A	P75
JTAG_TCK	Input	JTAG TCK	N/A	N/A	P77
JTAG_SI	Input	JTAG SI	N/A	N/A	P100
JTAG_SO	Output	JTAG SO	N/A	N/A	P76

LED's

The Papilio One has a power LED, a RX LED, and a TX LED. The power led lights up to indicate that power is being supplied to the board while the RX and TX led's show UART traffic.
